(54) Abstract Title

Telemetry system in which data signals are modulated on power signals

(57) A telemetry system is capable of transmitting both power and data signals between a master unit 10 and at least one slave unit 50 (a,b) over a transmission system 12 which is part of a borehole, an oil well or a pipeline which may be a subsea installation. The transmission system comprises a tubing string or pipeline incorporating electrically isolating collars 200 a,b. A well casing or another pipeline may provide an earth/return path, the slave unit 50 being coupled between the tubing string and the well casing or between the two pipelines. The master unit 10 may use pulse width modulation of a power signal from driver 24 to send data to the slave unit 50. Power signals received by the slave unit are fed to regulators 56,58 to provide a local power supply for the slave unit. Data signals from the slave unit may be encoded by frequency shift keying at generator 64, synchronised with the pulses of the power signal, for transmission to the master unit. Data signals sent from the master unit may be detected by a timer circuit 70 and used to control valves, actuators or motors, while the data signals from the slave unit may represent the outputs of sensors. The data signals may be encrypted, e.g. using a Hamming code.

1     **"Telemetry System"**

2

3     The present invention relates to a telemetry system,  
4     particularly for use with an isolated pipeline or  
5     tubing string.

6

7     Telemetry systems are typically used in the oil and  
8     gas industry to transmit data from measuring devices,  
9     sensors or the like located downhole to receivers  
10    located at the surface. Conventional systems use  
11    transmission mediums such as drilling fluid or mud in  
12    which to transmit the signals between downhole and  
13    surface locations. In addition, mono-conductor  
14    instrument cables and single- or three-phase power  
15    cables are often used to transmit data communications  
16    in addition to their primary function.

17

18    Such conventional systems typically require at least  
19    two individual power sources: one at the surface to  
20    drive the receiving circuitry, and at least one

1 downhole to drive the remote circuitry. This  
2 duplication of power sources increases the cost of  
3 the system and may make the system unreliable, as  
4 more components are required.

5  
6 Furthermore, the power source downhole has  
7 limitations associated with it in that the power  
8 output from the source is restricted due to the  
9 remoteness of the source. For example, the downhole  
10 power source may comprise batteries that have a  
11 limited power output and also a limited lifetime  
12 before they must be either replaced or recharged.

13  
14 A typical production completion requires a mono  
15 conductor cable to be installed during the completion  
16 in order to recover signals or perform control of  
17 downhole devices. The installation of this cable  
18 creates cost and complexity in the completion design.

19  
20 According to a first aspect of the present invention  
21 there is provided a telemetry system, the system  
22 comprising a master unit, and at least one slave unit  
23 remote from the master unit, the master and slave  
24 units communicating via a transmission system,  
25 wherein the telemetry system is capable of  
26 transmitting power and data transmissions between the  
27 units, and wherein the transmission system includes  
28 an at least partially isolated tubing string or  
29 pipeline.

30

1 According to a second aspect of the present  
2 invention, there is provided a method of transmitting  
3 power and data from a master unit to at least one  
4 slave unit remote from the master unit, the master  
5 and slave units communicating via a transmission  
6 system, the transmission system including an at least  
7 partially isolated pipeline or tubing string, the  
8 method comprising the steps of

9 generating a power transmission at the master  
10 unit;  
11 generating a data transmission and synchronising  
12 the data transmission with the power  
13 transmission at the master unit;  
14 transmitting the power and data transmissions  
15 via the transmission system to the slave unit;  
16 and  
17 recovering the power and data transmissions at  
18 the slave unit.

19  
20 According to a third aspect of the present invention,  
21 there is provided a method of transmitting data to a  
22 master unit from at least one slave unit remote from  
23 the master unit, the master and slave units  
24 communicating via a transmission system, the  
25 transmission system including an at least partially  
26 isolated tubing string or pipeline, the method  
27 comprising the steps of

28 generating a power transmission at the master  
29 unit and transmitting the power transmission to  
30 the slave unit;

1       recovering the power transmission at the slave  
2       unit;  
3       generating a data transmission at the slave unit  
4       and synchronising the data transmission with the  
5       power transmission;  
6       transmitting the data transmission via the  
7       transmission system to the master unit; and  
8       recovering the data transmission at the master  
9       unit.

10

11       Optionally, the method may include the further steps  
12       of

13           dividing the data transmission into a series of  
14       sub-windows;

15           transmitting a specified data transmission from  
16       the slave unit to the master unit;

17           receiving the specified data transmission at the  
18       master unit;

19           determining which of the sub-windows reliably  
20       transmitted the specified data transmission.

21

22       The sub-windows that did not reliably transmit data  
23       are typically filtered out or ignored for subsequent  
24       transmissions. This technique may be used where the  
25       transmission system is particularly noisy or may be  
26       subject to interference and increases the chances of  
27       reliably retrieving data transmissions.

28

29       According to a fourth aspect of the present  
30       invention, there is provided a method of receiving  
31       and converting power and data transmissions sent from

1 a master unit to at least one slave unit remote from  
2 the master unit, the master and slave units  
3 communicating via a transmission system, the  
4 transmission system including an at least partially  
5 isolated pipeline or tubing string, the method  
6 comprising the steps of  
7 receiving a power transmission at the slave  
8 unit;  
9 dividing the power transmission into two  
10 channels;  
11 rectifying and regulating the power transmission  
12 in a first channel; and  
13 recovering the data transmission in a second  
14 channel.

15  
16 According to a fifth aspect of the present invention,  
17 there is provided a method of receiving data  
18 transmitted by a master unit from at least one slave  
19 unit remote from the master unit, the master and  
20 slave units communicating via a transmission system,  
21 the transmission system including an at least  
22 partially isolated pipeline or tubing string, the  
23 method comprising the steps of  
24 receiving the data transmission at the master  
25 unit;  
26 filtering and conditioning the data  
27 transmission; and  
28 regenerating the transmitted data.

29  
30 Optionally, the method may include the further steps  
31 of

1       dividing the data transmission into a series of  
2 sub-windows;  
3       transmitting a specified data transmission from  
4 the slave unit to the master unit;  
5       receiving the specified data transmission at the  
6 master unit;  
7       determining which of the sub-windows reliably  
8 transmitted the specified data transmission.

9  
10 The sub-windows that did not reliably transmit data  
11 are typically ignored for subsequent transmissions.  
12 This technique may be used where the transmission  
13 system is particularly noisy and increases the  
14 chances of reliably retrieving data transmissions.

15  
16 The pipeline or tubing string is typically  
17 electrically isolated using at least one isolating  
18 collar. The isolating collar typically comprises  
19 first and second connectors, the first and second  
20 connectors being threadedly coupled together.  
21 Preferably, an electrical isolating material is  
22 injected between the first and second connectors to  
23 isolate the connectors from one another. The  
24 insulating material is typically epoxy or the like.

25  
26 The isolating collar typically includes means for  
27 conveying electrical signals from outwith the collar  
28 to the second connector. Thus, any pipeline or  
29 tubing string coupled to the second connector is  
30 typically capable of carrying electrical signals.

31

1 The pipeline or tubing string is typically coated  
2 with an electrical isolating paint or the like to at  
3 least partially isolate the pipeline or tubing  
4 string.

5  
6 The at least partially isolated pipeline or tubing  
7 string typically comprises a surface pipeline or  
8 tubing string. Alternatively, the at least partially  
9 isolated pipeline or tubing string comprises a subsea  
10 pipeline or tubing string, or a downhole pipeline or  
11 tubing string. It will be appreciated that the at  
12 least partially isolated pipeline or tubing string  
13 may further comprise any combination of surface,  
14 subsea or downhole pipelines or tubing strings.

15  
16 The pipeline or tubing string typically includes a  
17 first isolating collar at or near a source of fluid  
18 flowing within the pipeline or tubing string.  
19 Optionally, the pipeline or tubing string includes a  
20 second isolating collar at or near a sink for the  
21 fluid in the pipeline or tubing string. The master  
22 unit is typically electrically coupled to the  
23 pipeline or tubing string via the first isolating  
24 collar. At least one slave unit is coupled to the  
25 pipeline or tubing string, preferably at one or more  
26 locations between said first and second isolating  
27 collars.

28  
29 System components including the master and slave  
30 units may be earthed by being connected to a local  
31 earth. Alternatively, a system earth and/or

1    electrical return path may be provided by other  
2    tubulars such as a second pipeline or tubing string  
3    or by a downhole, surface or subsea casing or the  
4    like surrounding the pipeline or tubing string.

5  
6    The slave unit typically comprises a mandrel, a slave  
7    module, and an electrical return path. The mandrel  
8    typically facilitates attachment of the slave unit to  
9    the pipeline or tubing string. The mandrel is  
10   typically clamped, or otherwise coupled, to the  
11   pipeline or tubing string. The mandrel typically  
12   facilitates transmission of the electrical power and  
13   data transmissions from the pipeline to the  
14   electronics of the slave unit.

15  
16   The slave module typically houses the electronics of  
17   the slave unit. The electrical return path typically  
18   comprises a spring contact for engaging an earth  
19   point. The earth point may be a local earth, a  
20   further tubular such as a second pipeline, a subsea  
21   or surface casing or a casing of a downhole well.

22  
23   The slave unit is typically coupled to the pipeline  
24   using a mandrel, pipeline clamp or other conventional  
25   means. The pipeline or tubing string typically  
26   includes a wellhead. A first isolating collar is  
27   typically located at or near the wellhead. The  
28   master unit is typically electrically coupled to the  
29   first isolating collar (and thus the isolated  
30   pipeline or tubing string) via a wellhead penetrator.  
31   Alternatively, the master unit may be electrically

1 coupled to the pipeline by directly attaching the  
2 output of the master unit to the pipeline using a  
3 pipeline clamp, or other conventional attachment  
4 means, for example a tubing clamp provided with a  
5 cable coupling.

6  
7 Pulse-width modulation is typically used to  
8 facilitate data transmission from the master unit to  
9 the slave unit. The power transmission is typically  
10 modulated with the data transmission using pulse-  
11 width modulation.

12  
13 Frequency-shift keying (FSK) is typically used to  
14 facilitate data transmission from the slave unit to  
15 the master unit. The FSK frequencies are typically  
16 superimposed on a carrier frequency. The carrier  
17 frequency is typically the same frequency as the  
18 power transmission frequency. The data transmission  
19 is typically synchronised to the "high" cycle of the  
20 power transmission. Alternatively, the data  
21 transmission may be synchronised to the "low" cycle  
22 of the power transmission, or optionally to both the  
23 low and high cycles, or to any range of cycles to  
24 circumvent the range of interference.

25  
26 Where more than one slave unit is used, the data  
27 transmission from the master unit to the slave unit  
28 typically includes an address of the slave unit.  
29 This allows several slave units to receive commands  
30 from a single master unit.

31

1 The data transmissions preferably include data error  
2 detection and/or correction. The data error  
3 detection and/or correction typically comprise a  
4 Hamming code, or other suitable technique.  
5 Optionally where no DC or secondary power source is  
6 in the system the master and slave may optionally be  
7 DC coupled.

8  
9 The master unit and/or the slave unit are preferably  
10 ac coupled to the transmission system using  
11 capacitors. Most preferably, the system employs  
12 separate and discrete capacitors for this purpose.  
13 This is known as capacitive coupling and allows any  
14 dc bias within the transmissions to be blocked,  
15 whilst passing any ac signals.

16  
17 The master unit typically comprises a processor to  
18 control the operation of the master unit; a power  
19 waveform generator; and signal recovery and  
20 conditioning circuitry.

21  
22 The processor typically applies pulse-width  
23 modulation to the power transmission when data  
24 transmission is required from the master unit to the  
25 slave unit. When not transmitting data, the  
26 processor typically defaults the power transmission  
27 to a 50% duty cycle.

28  
29 The power waveform generator typically comprises an  
30 analogue driver, and a power drive electrically  
31 coupled to the analogue driver. The processor

1 typically applies the power transmission to the  
2 analogue driver. The analogue driver typically  
3 drives the power driver. The processor typically  
4 controls the voltage amplitude of the power  
5 transmission.

6  
7 The analogue driver typically includes an isolating  
8 circuit that isolates the power driver from the  
9 processor. Typically, the analogue driver further  
10 includes low voltage logic drivers to high voltage  
11 driver stages, which in turn drive the power driver.  
12 This prevents any damage being caused to the  
13 processor.

14  
15 The power driver typically comprises a field-effect  
16 transistor (FET) based push-pull driver.  
17 Alternatively, the power driver comprises a bi-polar  
18 transistor based push-pull driver, or the like. The  
19 power driver typically operates from a variable dc  
20 power supply. The master unit typically includes the  
21 variable dc power supply.

22  
23 The signal recovery and conditioning circuitry  
24 typically allows data transmitted by the at least one  
25 slave unit to be extracted and recovered from the  
26 transmission system. The signal recovery circuit  
27 typically includes first and second data channels.  
28 The first data channel typically includes a high-  
29 speed switch; a filtering system; an automatic gain  
30 control (AGC) stage; a comparator stage; and a first  
31 counter.

1

2 The high-speed switch typically enables the data  
3 transmission to be directed to the first and/or  
4 second data channels when the power transmission is  
5 high. Alternatively, the high-speed switch directs  
6 the data transmission to the first and/or second data  
7 channels when the power transmission is low, or when  
8 the power transmission is both high and low.

9

10 The filtering system typically removes any noise and  
11 background signals from the recovered data.

12 Typically, the filtering system comprises a pair of  
13 selective filters. The selective filters typically  
14 comprise broad bandpass filters. Alternatively, the  
15 selective filters may comprise tuned filters. This  
16 allows the filters to differentiate between the FSK  
17 frequencies.

18

19 The AGC stage typically maintains the signal within a  
20 set voltage amplitude range.

21

22 The comparator stage typically compares the voltage  
23 amplitudes of the FSK frequencies.

24

25 The slave unit typically comprises a processor to  
26 control the operation of the slave unit; rectifying  
27 and regulating circuitry in a first channel; recovery  
28 and conditioning circuitry in a second channel; and  
29 frequency generating and mixing means.

30

1 The rectifying and regulating circuitry typically  
2 comprises a half-bridge rectifier to rectify the  
3 received power transmission into a dc voltage; and at  
4 least one voltage regulator to regulate the dc  
5 voltage.

6  
7 The recovery and conditioning circuitry typically  
8 comprises an amplifier and filtering system; and a  
9 timer circuit. The amplifier and filtering system  
10 typically amplifies or attenuates the signal, and  
11 filters the signal. This boosts the amplitude of the  
12 signal and removes any background noise or other  
13 interference.

14  
15 The frequency mixing and generating means typically  
16 comprises a frequency-shift keying (FSK) generator;  
17 an FSK mixer; and a line driver.

18  
19 The slave unit typically includes an analogue signal  
20 conditioning circuit, and at least one analogue-to-  
21 digital convertor. The analogue conditioning circuit  
22 allows the slave unit to receive and process signals  
23 from a plurality of sensors, such as pressure  
24 sensors, temperature sensors or the like.

25  
26 The slave unit is typically capable of controlling  
27 loads.

28  
29 Embodiments of the present invention shall now be  
30 described, by way of example only, with reference to  
31 the accompanying drawings, in which :-

1        Fig. 1 schematically illustrates an embodiment  
2        of a telemetry system coupled to an isolated  
3        pipeline;  
4        Fig. 2 schematically illustrates an embodiment  
5        of a telemetry system similar to that of Fig. 1  
6        with an additional slave unit;  
7        Fig. 3 is a schematic block diagram of a  
8        telemetry system in accordance with one  
9        embodiment of the present invention;

17 Fig. 11 is a schematic illustration of a portion  
18 of the oilwell of Fig. 9 showing connection of  
19 an electrical signal to a pipeline or tubing  
20 string;  
21 Fig. 12 is a cross-sectional elevation  
22 illustrating an embodiment of a slave unit of  
23 the telemetry system of Fig. 2 attached to an  
24 isolated pipeline or tubing string;  
25 Figs 13a and 13b schematically illustrate a  
26 subsea pipeline installation with dual and  
27 single pipelines, respectively, with the  
28 telemetry system of Fig. 2 attached thereto;  
29 Fig. 14 is a cross-sectional elevation  
30 illustrating a method of attaching a slave unit  
31 to a subsea pipeline;

1 Figs 15a and 15b schematically illustrate a  
2 surface pipeline installation with dual and  
3 single pipelines, respectively, with the  
4 telemetry system of Fig. 2 attached thereto;  
5 Fig. 16 schematically illustrates a method of  
6 attaching a slave unit to a surface pipeline;  
7 and  
8 Fig. 17 schematically illustrates an oilwell  
9 that has a subsea or surface pipeline attached  
10 thereto.

11  
12 Referring to the drawings, Fig. 1 shows an  
13 illustrative embodiment of an exemplary embodiment of  
14 a telemetry system coupled to an isolated pipeline or  
15 the like according to the present invention. As  
16 shown more clearly in Fig. 3, the telemetry system  
17 comprises a master unit 10 and a slave or node unit  
18 50. The master and slave units 10, 50 communicate  
19 with each other via a transmission system 12, i.e. a  
20 pipeline or well tubing string 100 (Fig. 1), that is  
21 at least partially isolated from earth, e.g. by means  
22 of at least one isolating collar 200 (Figs 4 and 5).  
23 In the embodiment shown in Fig. 1, a first isolating  
24 collar 200a is located at a first end of the pipeline  
25 100. Optionally, a second isolating collar 200b may  
26 be positioned at a distal end of the pipeline 100 at  
27 the end of a transmission zone, the transmission zone  
28 being defined between the first and second isolating  
29 collars 200a, 200b.

30

1 The master unit 10 typically includes a power supply  
2 and controller unit that generates an electrical  
3 power supply, and also transmits data to and receives  
4 data from the remote slave unit 50. The slave unit  
5 50 is powered by the master unit 10 as will be  
6 described hereinafter, and can carry out control and  
7 monitoring functions from where it is coupled to the  
8 isolated pipeline 100. The master and slave units  
9 10, 50 require the electrical circuit to be completed  
10 by connection to an electrical ground or earth point,  
11 as schematically shown in Fig. 1.

12  
13 In this way, sensors, instrumentation systems or load  
14 actuators coupled to the slave unit 50 can be  
15 monitored and the load actuators can be controlled  
16 from the master unit 10 using only the pipeline 100  
17 for transmission of power and data transmissions.  
18 Further the slave unit 50 can be coupled at any point  
19 in the isolated portion of the pipeline 100 (i.e. the  
20 transmission zone defined between isolating collars  
21 200a, 200b).

22  
23 As shown in Fig. 2, the system can support more than  
24 one slave unit (i.e. slave units 50a, 50b) coupled to  
25 the isolated portion of the pipeline 100. The system  
26 can support multiple slave units 50a, 50b etc, with  
27 each slave unit 50a, 50b etc, being coupled to the  
28 pipeline 100 at any point in the isolated portion.

29  
30 The system may be configured to transmit either  
31 solely the power supply transmissions from the master

1 unit 10 to the slave unit 50, or to include data  
2 transmissions in addition to transmitting power. The  
3 data transmission is typically synchronised to the  
4 power supply transmission and/or with a secondary and  
5 larger power source running in parallel with the  
6 power supply and data transmissions from the master  
7 unit 10 to the slave units 50. This secondary power  
8 source can either be used for pipeline heating and/or  
9 powering large power actuators and motors attached to  
10 the isolated portion of the pipeline 100.

11  
12 The master unit 10 is typically located at the  
13 surface, and the slave unit 50 is typically located  
14 remote from the master unit 10, for example in a  
15 borehole, oilwell, subsea installation or the like.  
16 The location of the master unit 10 is dependent upon  
17 the particular application, and the relative  
18 positions of the master unit 10 and the slave unit(s)  
19 50 described herein are by way of example only.

20  
21 It should be noted that a number of slave units 50  
22 may be coupled to the transmission system 12 (i.e.  
23 the pipeline 100), and the operation of each slave  
24 unit 50 controlled by the master unit 10 at the  
25 surface. It should also be noted that the system may  
26 use more than one master unit 10 if control of the  
27 slave unit(s) 50 is required from more than one point  
28 in the system.

29  
30 The master and slave units 10, 50 are advantageously  
31 coupled to the isolated pipeline 100 using capacitive

1 coupling. Discrete capacitors 14, 52 (Fig. 3) are  
2 coupling or blocking capacitors that couple a signal  
3 from a power source (discussed later) to the isolated  
4 pipeline 100. Capacitors 14, 52 block any direct  
5 current (dc) bias that may be applied to the signal,  
6 but do not affect any alternating current (ac) signal  
7 that is simultaneously transmitted. When considering  
8 dc, the capacitors 14, 52 act as open circuits as, at  
9 zero frequency (dc), the reactance of a capacitor is  
10 infinite.

11  
12 Referring now to Fig. 3, the master unit 10 includes  
13 a power input stage 16 that provides power for the  
14 telemetry system, and may be either an ac or dc power  
15 source. The power input stage 16 is electrically  
16 coupled to at least one (and preferably a plurality  
17 of) dc voltage regulators 18. Voltage regulators 18  
18 provide local power supplies (dc) for the circuitry  
19 in the master unit 10. Generally, different  
20 components within the master and slave units 10, 50  
21 operate using a plurality of different voltages,  
22 depending upon the various specifications of these  
23 components.

24  
25 The master unit 10 includes a processor 20 that,  
26 among other functions, controls the operation of the  
27 telemetry system. One output of the processor 20 is  
28 electrically coupled to an analogue driver stage 22,  
29 the driver stage 22 being electrically coupled to a  
30 high voltage ac power driver 24. The output of the

1 power driver 24 is electrically coupled (via the  
2 coupling capacitor 14) to the isolated pipeline 100.

3  
4 The power driver 24 may be a field-effect transistor  
5 (FET) or a bi-polar transistor based push-pull drive  
6 stage, that typically operates using a variable but  
7 relatively large dc voltage power supply. The dc  
8 power supply is typically rated from 20 to 500 volts,  
9 although voltages outwith this range may also be  
10 used. The particular voltage used is dependent upon  
11 the loading conditions and losses in the isolated  
12 pipeline 100, and can be varied accordingly.

13  
14 The power driver 24 is preferably electrically  
15 isolated from the processor 20 to prevent damage to  
16 the processor 20. Thus, the analogue driver stage 22  
17 includes isolating circuits and low voltage logic  
18 drivers to a high voltage drive stage, which in turn  
19 drives the gates of the FET or bi-polar transistor  
20 power driver 24.

21  
22 The master unit 10 further includes a signal recovery  
23 circuit 26 that retrieves data transmitted (via the  
24 isolated pipeline 100 as will be described) by the  
25 slave unit 50. The processor 20 controls operation  
26 of the signal recovery circuit 26. The recovered  
27 data from the signal recovery circuit 26 is processed  
28 by a filtering system 28 that further extracts the  
29 received information from any noise or other  
30 background interference mixed with the recovered data  
31 from the slave unit 50.

1

2 The output from the filtering system 28 is fed into a  
3 signal conditioning unit that includes an automatic  
4 gain control (AGC) stage 30, and a comparator stage  
5 32. The output of the comparator stage 32 is fed  
6 into a first counter 34. The first counter 34 is  
7 electrically coupled to the processor 20, so that the  
8 processor 20 can read the value in the first counter  
9 34.

10

11 In certain embodiments of the present invention, the  
12 raw signal from the slave unit 50 is additionally fed  
13 into a second data channel that includes a signal  
14 recovery circuit 36 to extract data from the power  
15 transmission on the isolated pipeline 100. The  
16 output from the second signal recovery circuit 36 is  
17 fed into a timer circuit 38 that performs pulse-width  
18 measurements on the data extracted from the power  
19 transmission. The output of the timer circuit 38 is  
20 fed into a second counter 40, the value in the  
21 counter being read by the processor 20.

22

23 A remote station (not shown) typically controls  
24 operation of the master unit 10, and is electrically  
25 coupled to the master unit 10 via a serial data link  
26 46, such as an RS232/485 serial data port. The  
27 remote station may be, for example, a personal  
28 computer located remotely from the master unit 10.

29

30 The slave unit 50 includes a half-wave rectifier and  
31 heat dissipation unit 54. This unit 54 extracts

1 power transmitted via the isolated pipeline 100 to  
2 the slave unit 50 as will be described. As with the  
3 master unit 10, the slave unit 50 has a matched pair  
4 of voltage regulators 56 and a plurality of low  
5 voltage dc regulators 58 to provide local power  
6 supplies for the circuitry in the slave unit 50.

7  
8 The slave unit 50 is provided with a processor 60 to  
9 control the operation thereof. The processor 60 is  
10 electrically coupled to a line driver 62 that  
11 transmits data onto the isolated pipeline 100.

12  
13 In certain embodiments, the slave unit 50 transmits  
14 data to the master unit 10 (via the isolated pipeline  
15 100) using frequency-shift keying (FSK), as will be  
16 described. A frequency generator 64 is used to  
17 generate the two required frequencies  $F_1$ ,  $F_2$ . The  
18 frequencies  $F_1$ ,  $F_2$  are then mixed by a frequency mixer  
19 66 to combine data from the processor 60 with carrier  
20 frequency  $F_c$  and the modulating frequencies  $F_1$ ,  $F_2$ .

21  
22 The slave unit 50 further includes a signal recovery  
23 circuit 68 to extract data from the isolated pipeline  
24 100 generated by the master unit 10. A timer circuit  
25 70 is used to perform pulse-width measurements on the  
26 data extracted by the signal recovery circuit 68.

27  
28 The slave unit 50 is provided with an analogue signal  
29 conditioning circuit 74, and a plurality of analogue-  
30 to-digital (A/D) convertors 76. The analogue  
31 conditioning circuit 74 and the A/D convertors 76

1 allow a plurality of different types of  
2 instrumentation and/or sensors (not shown) to be  
3 coupled to the system. Thus, the slave unit 50  
4 monitors these instruments and sensors and transmits  
5 data procured by them to the master unit 10 for  
6 collection and analysis.

7  
8 The slave unit 50 can accept a wide range of sensors,  
9 and any electronic sensor that can be conditioned and  
10 measured using a processor can be used with the  
11 system. Typical sensor inputs to the analogue signal  
12 conditioning circuit 74 comprise either analogue  
13 sensors with voltage outputs, or those with frequency  
14 outputs. Typical examples of analogue sensors that  
15 may be used to collect information include pressure  
16 sensors, temperature sensors, accelerometers and  
17 fluid depth sensors (resistive or capacitive).  
18 Typical examples of frequency or pulse output  
19 sensors, include shaft speed indicators, high  
20 accuracy pressure and temperature sensors and flow  
21 meters. These are exemplary only, and the range of  
22 applications will be apparent to those skilled in the  
23 art.

24  
25 The analogue sensors coupled to the system can be  
26 powered from the low-level regulators 58 in the slave  
27 unit 50. The voltage or current outputs from the  
28 sensors would be amplified or filtered in the  
29 analogue signal conditioning circuit 74 if required,  
30 and the conditioned outputs fed into the multiplexed

1 A/D convertor 76, the outputs then being fed to the  
2 processor 60 for transmission in digital format.

3  
4 The data system architecture within the system  
5 typically operates using 16 or 24 bit data words for  
6 transmission, and read values can be transmitted to  
7 the master unit 10 as A/D counts in either 16 or 24  
8 bit words, depending upon the required accuracy and  
9 resolution of the measurements.

10  
11 Where pulse or frequency signals are output from the  
12 sensors, a reciprocal counter could be used to  
13 measure the frequency locally in the analogue signal  
14 conditioning unit 74. In this embodiment, the  
15 processor 60 typically forms part of the reciprocal  
16 counter to minimise or reduce the electronics  
17 required in the slave unit 50.

18  
19 In addition to sensor measuring capabilities, the  
20 system could be utilised to control loads. As the  
21 system in certain embodiments can facilitate two-way  
22 communication, any electronic control that can be  
23 implemented with the local processor 60 can be  
24 implemented using the telemetry system. For example,  
25 the slave unit 50 may be used to control solenoids to  
26 operate and control actuators, hydraulic valve  
27 mechanisms, motors that open valves, or other similar  
28 functions.

29  
30 Operation of the telemetry system shall now be  
31 described. The processor 20 in the master unit 10

1 applies a power waveform to the driver 22 under  
2 command from the remote station. The driver 22  
3 drives the power driver 24 that applies a square-wave  
4 power waveform (Fig. 6a), the power waveform being  
5 transmitted to the isolated pipeline 100 through the  
6 coupling capacitor 14.

7  
8 Fig. 6a shows an exemplary power signal waveform that  
9 is transmitted from the master unit 10 to the slave  
10 unit 50 via the isolated pipeline 100. The frequency  
11 of the waveform may be any suitable frequency; a  
12 typical frequency range may be from 10 millihertz  
13 (mHz) to 6 kilohertz (kHz) although frequencies  
14 outwith this range may be used. Where there is even  
15 a moderate bandwidth on the isolated pipeline 100,  
16 the frequencies used to transmit power from the  
17 master unit 10 to the slave unit 50 will be from 100  
18 Hz to 100 kHz.

19  
20 The amplitude of the waveform is variable and is  
21 dependent upon the loading conditions and losses of  
22 the isolated pipeline 100. The processor 20 using a  
23 regulator (one of the plurality of regulators 18)  
24 controls the voltage amplitude of the square-wave  
25 power waveform (Fig. 6a). By controlling the  
26 amplitude of the power waveform using a processor 20,  
27 the amplitude may be adjusted either manually or  
28 automatically to set and keep the amplitude constant  
29 in varying operating conditions.

30

1 The slave unit 50 receives an attenuated power input  
2 from the isolated pipeline 100 through the coupling  
3 capacitor 52. Any background noise or other  
4 interference will be added to the power signal during  
5 transmission from the master unit 10 to the slave  
6 unit 50, thus resulting in a degraded signal being  
7 detected at the slave unit 50. The power is  
8 rectified through the half-bridge rectifier 54 and is  
9 then regulated in the regulating units 56, 58 to  
10 provide the local power supplies for the various  
11 circuitry within the slave unit 50.

12

13 Fig. 6b illustrates how data may be transmitted from  
14 the slave unit 50 to the master unit 10. Data is  
15 transmitted using frequency-shift keying (FSK) in a  
16 continuous stream during data transmission. Two FSK  
17 frequencies  $F_1$ ,  $F_2$  are superimposed on a carrier  
18 frequency  $F_c$ . In the example shown in Fig. 6b, the  
19 carrier frequency  $F_c$  is the same frequency as the  
20 power waveform of Fig. 6a, and the data transmission  
21 is synchronised to the "high" cycle of the power  
22 waveform shown in Fig. 6a. It should be noted that  
23 the data may be synchronised to the "low" cycle, or  
24 to both the high and low cycles. This  
25 synchronisation allows the master unit 10 to  
26 correctly detect the data transmission from the slave  
27 unit 50.

28

29 The frequencies used to transmit data from the slave  
30 unit 50 are typically several hundred kilohertz  
31 (kHz). For example, the transmit frequencies  $F_1$ ,  $F_2$

1 from the slave unit 50 to the master unit 10 may be  
2 300 kHz for a logic one and 100 kHz for a logic zero.  
3 Thus, if a logic one is to be transmitted, then the  
4 higher of the two FSK frequencies (i.e.  $F_1$ ) will be  
5 transmitted for the duration of the high cycle of the  
6 power waveform, and if a logic zero is to be  
7 transmitted, the lower of the two FSK frequencies  
8 (i.e.  $F_2$ ) is transmitted for the duration of the high  
9 cycle of the power waveform.

10

11 The two FSK frequencies  $F_1$ ,  $F_2$  are preferably not  
12 multiples of one another to minimise the occurrence  
13 of false detections. The two frequencies  $F_1$ ,  $F_2$  are  
14 typically also at least a factor of two different.  
15 Although this increases the amount of bandwidth  
16 required on the isolated pipeline 100, it allows for  
17 the recovery of highly attenuated signals. Where  
18 there is significant inductance on the isolated  
19 pipeline 100, much lower frequencies may be used.  
20 This reduces the speed of the system, but does not  
21 affect the ability of the system to transmit and  
22 receive data. Low carrier frequencies may be used  
23 (in the order of a few hertz) with very high  
24 frequency data carriers to increase data recovery in  
25 noisy environments, such as that downhole. Where low  
26 frequencies are required, the system may also be used  
27 with fractions of a hertz for the carrier, and a  
28 logic zero frequency of 100 Hz and a logic one  
29 frequency of 350 Hz, for example.

30

1 Power across the slave unit 50 can be adjusted to  
2 provide the power supplies necessary for the type of  
3 electronics being operated. For example, for any  
4 instrument systems being operated downhole,  $\pm 15$  volts  
5 is normally required. Thus, the ac power across the  
6 (downhole) slave unit 50 will be in the order of  $\pm 30$   
7 volts to maintain the power supplies at a stable  
8 level (due to losses etc).

9  
10 The data recovery circuit 26 in the master unit 10  
11 operates as follows. The low-level signal  
12 transmitted by the slave unit 50 is sensed using a  
13 sense resistor 42. The signal from the slave unit 50  
14 develops a voltage across the sense resistor 42 as  
15 the output of the push-pull power driver 24 is  
16 effectively an ac ground.

17  
18 The value of sense resistor 42 is typically twenty  
19 times the resistive value of the isolated pipeline  
20 100. For example, if the resistive value of the  
21 isolated pipeline 100 is 10 ohms ( $\Omega$ ) from a master  
22 injection point 44 (Fig. 3) to the slave unit 50,  
23 then the sense resistor 42 would have a value of  
24  $200\Omega$ . The value of this sense resistor 42 can be  
25 chosen to match the particular isolated pipeline 100.

26  
27 The raw signal from the sense resistor 42 is then  
28 processed by the first data channel that includes the  
29 first signal recovery circuit 26, and is fed through  
30 an analogue high speed switch (not shown, but forms  
31 part of the signal recovery circuit 26). The

1 processor 20 or a local zero-crossing detection  
2 circuit or the like, enables data to be directed to  
3 the first data channel only when the power waveform  
4 is high, thus facilitating the synchronisation. The  
5 data channel then only receives and processes valid  
6 segments of the recovered data. It should be noted  
7 that the triggering mechanism for directing data into  
8 the data channel may be configured to allow  
9 transmission when the power waveform is low, or both  
10 when it is high and low.

11

12 The sampled data is then fed through the filtering  
13 system 28 that, in simple applications, typically  
14 comprises a single broad bandpass filter. In noisy  
15 applications, it is preferable to use a pair of  
16 selective filters designed for each transmit  
17 frequency  $F_1$ ,  $F_2$ . It may also be necessary in  
18 exceptionally noisy environments to use tuned  
19 filters.

20

21 The signal recovered from the filtering system 28 is  
22 then fed through an automatic gain control (AGC)  
23 stage 30. The AGC stage 30 maintains the amplitude  
24 of the recovered signal within a set amplitude range.  
25 The frequency response of the AGC stage 30 is  
26 typically sufficient to allow the AGC amplifier to  
27 correct for changes in amplitude over one cycle of  
28 either the transmission medium power frequency or the  
29 telemetry system power frequency, whichever is the  
30 higher frequency. The AGC stage 30 performs two  
31 functions. It compensates for the difference in

1 amplitude from the high carrier to the low carrier  
2 frequency received (i.e. the difference in amplitudes  
3 between  $F_1$  and  $F_2$ ). In addition, there may also be  
4 variations in the amplitude of the received signal  
5 over the time period of the high cycle of the power  
6 waveform frequency (i.e. variations in amplitude of  
7 the signal during a single bit transmission). The  
8 AGC stage 30 must be able to react quickly enough to  
9 compensate for these changes without becoming  
10 unstable. Thus, the frequency response of the AGC  
11 stage 30 is related to the frequency of the power  
12 waveform, and the bandwidth of the AGC stage 30 is  
13 typically ten times greater than the power waveform  
14 frequency (i.e. ten times greater than the baud  
15 rate).

16  
17 The recovered signal is then fed into the comparator  
18 stage 32, the output of which is fed into the first  
19 counter 34. The comparator stage 32 compares the  
20 signal level of each of the two FSK frequencies  $F_1$ ,  
21  $F_2$  to establish which is present. The output of the  
22 comparator stage 32 is a signal that contains either  
23 one of the two FSK frequencies  $F_1$ ,  $F_2$ . The first  
24 counter 34 then counts the number of pulses in the  
25 signal from the comparator stage 32, and the  
26 processor 20 reads the value in the first counter 34  
27 to determine which of the two FSK logic frequencies  
28  $F_1$ ,  $F_2$  are present (i.e. either the frequency  
29 relating to a logic one or zero).

1 The slave unit 50 transmits in a continuous stream of  
2 digital data (i.e. ones and zeros), with each high  
3 cycle of the power waveform containing one of the two  
4 FSK frequencies  $F_1$ ,  $F_2$  representing either a logic  
5 one or zero. The process is thus continued for each  
6 high cycle of the power waveform to determine whether  
7 a one or a zero was transmitted in each high cycle.  
8 Once the processor 20 has determined whether a one or  
9 a zero was sent in each high cycle, the processor 20  
10 may reconstruct the transmitted digital data from the  
11 slave unit 50.

12  
13 The slave unit 50 may also transmit bursts of  
14 transmitted data in a poll response mode. In the  
15 poll response mode, there are three states for  
16 transmission from the slave unit 10 to the master  
17 unit 50: a logic one, a logic zero and a "none"  
18 state. Thus, when not requested to transmit data the  
19 slave unit 50 ceases transmission. This poll  
20 response mode is typically used where multiple slave  
21 units 50 are operating on the same transmission  
22 system.

23  
24 Figs 7a and 7b illustrate a power and data  
25 transmission waveform respectively, for the  
26 transmission of data from the master unit 10 at the  
27 surface to the slave unit 50. Data is transmitted  
28 from the master unit 10 to the slave unit 50 using  
29 pulse-width modulation. Use of this technique allows  
30 the signal recovery circuitry in the slave unit 50  
31 located downhole to be less complex than that in the

1 master unit 10, thus reducing the size, cost and  
2 power consumption of the slave unit 50.

3

4 Fig. 7a illustrates the power waveform transmitted  
5 when data is being transmitted from the master unit  
6 10 to the slave unit 50. In order to transmit  
7 digital data, the width of the pulses in the waveform  
8 are modified to represent either a digital zero or  
9 one. This technique is termed pulse-width  
10 modulation. Fig. 7b illustrates the difference in  
11 pulse-widths between a logic one and zero as an  
12 example. There are typically three different pulse-  
13 widths (frequencies) used, each relating to either a  
14 logic one, a logic zero or an idle state. The idle  
15 state is typically used to aid specific command  
16 recovery in the slave units 50. For example, where  
17 there is more than one slave unit 50 coupled to the  
18 system, each unit 50 remains in the idle state and  
19 polls the data transmissions from the master unit 10  
20 until it receives a command intended for that  
21 particular unit 50 identified by the command string.

22

23 When data is transmitted from the master unit 10 to  
24 the slave unit 50 using pulse-width modulation, the  
25 signal received at the slave unit 50 is fed through a  
26 second ac coupling capacitor 72 into a signal  
27 recovery circuit 70, that includes an amplifier and  
28 filtering system. The signal is amplified or  
29 attenuated, depending upon the application.

30

1 The relative frequency of the main transmission  
2 system power, and the frequency of the telemetry  
3 power carrier  $F_c$  determine the value of the coupling  
4 capacitor 72. The value is chosen so that the  
5 capacitive decoupling acts as a high pass filter to  
6 remove substantially all of the transmission system  
7 power waveform whilst recovering as much of the  
8 telemetry system power waveform as possible.

9

10 The requirement to either attenuate or amplify the  
11 signal after decoupling depends upon the attenuation  
12 of the high pass filter described above. As the  
13 signal is superimposed on the power waveform, it will  
14 have a substantial peak-to-peak voltage at the slave  
15 unit 50 connection. If this large voltage signal is  
16 decoupled without any substantial losses, the  
17 recovered signal fed to the first stage amplifiers in  
18 the signal recovery circuit 68 will exceed the supply  
19 rails and will thus require to be attenuated.

20

21 However, if the signal is decoupled with a  
22 substantial amount of low frequency rejection (i.e.  
23 through a high pass filter), then the signal fed to  
24 the first stage amplifier will be relatively small  
25 and will thus require to be amplified. The  
26 requirement to amplify or attenuate the signal is  
27 dependent upon the relative frequency of the power  
28 waveform to the transmission medium frequency.

29

30 The recovered and filtered signal is then fed into a  
31 processor-controlled timer circuit 70. The timer

1 circuit 70 may be replaced by a re-triggered  
2 monostable. The timer circuit 70 allows pulse-width  
3 measurements to be taken to determine whether a one  
4 or a zero was sent. The processor 60 can then  
5 reconstruct the data transmission from the master  
6 unit 10 to the slave unit 50 by analysing and  
7 recording each pulse-width in turn to determine the  
8 sequence of ones and zeros in the data transmission.

9  
10 Data sent by the master unit 10 to the slave unit 50,  
11 or vice versa, is typically encrypted by use of a  
12 Hamming Code, or other suitable data error detection  
13 and correction encoding scheme. The data from the  
14 master unit 10 may also include the address of the  
15 slave unit 50 in the command string so that several  
16 slave units 50 may receive different and individual  
17 commands from a single master unit 10.

18  
19 Where the isolated pipeline 100 is particularly noisy  
20 or there is a large degree of background  
21 interference, it is often not possible to determine  
22 from the method described above whether a logic one  
23 or zero was transmitted. To overcome this, the  
24 recovered data is not measured as one of two  
25 frequencies in windows delineated from the power  
26 waveform, but each data detection window that is seen  
27 by the processor 20 at the surface is sub-divided  
28 into several sub-windows. Figs. 8a to 8d illustrate  
29 this technique.

30

1 To operate correctly using this sub-dividing  
2 technique, it is preferable to use a second data  
3 channel within the master unit 10 that includes the  
4 second signal recovery circuit 36, the timer circuit  
5 38 and the second counter 40.

6  
7 The telemetry system may be coupled to any isolated  
8 pipeline 100 or a tubing string. For example, it may  
9 be coupled to an existing pipeline that is used to  
10 recover hydrocarbons from a borehole, subsea well or  
11 the like. Fig. 8a shows a typical power waveform  
12 that may be present on the isolated pipeline 100 and  
13 may be, for example, a power waveform that is driving  
14 a downhole motor. The second data channel in the  
15 master unit 10 is used to determine the fundamental  
16 operating frequency of the power waveform for the  
17 downhole motor. The processor 20 within the master  
18 unit 10 uses the second counter 40 to establish the  
19 frequency at which the power waveform on the isolated  
20 pipeline 100 is operating, using a similar technique  
21 as described above to determine whether a zero or a  
22 one was sent. The processor 20 then synchronises the  
23 transmitted power for the slave unit 50 (waveform  
24 shown in Fig. 8b) to the same frequency, or a  
25 multiple thereof, as the power frequency of the  
26 isolated pipeline 100. Thus, the power and data  
27 transmissions are synchronised to the frequency of  
28 the power on the isolated pipeline 100 over which  
29 they are transmitted (i.e. they are synchronised with  
30 the source of the noise which can cause a loss of  
31 signal) thus reducing the effect of the noise.

1

2 Fig. 8b shows an exemplary power waveform for  
3 transmission of power and/or data from the master  
4 unit 10 to the slave unit 50. The waveform shown in  
5 Fig. 8b is similar to that shown in Fig. 6a and may  
6 operate over the same frequency range (i.e. in the  
7 order of a few mHz to several kHz).

8

9 Fig. 9c illustrates the data transmission from the  
10 slave unit 10 downhole to the master unit 50 at the  
11 surface. The waveform is similar to that shown in  
12 Fig. 6b wherein the data transmission is superimposed  
13 upon and synchronised to the high cycle of the power  
14 waveform. Although the example shows data being  
15 superimposed on and synchronised to the high cycle,  
16 it should be noted that data could also be  
17 superimposed on and synchronised to the low cycle or  
18 both.

19

20 Frequency-shift keying (FSK) is used to transmit data  
21 from the slave unit 50 to the master unit 10. In the  
22 example shown in Fig. 8c,  $F_1$  that represents a logic  
23 one is 200 kHz and  $F_2$  that represents a logic zero is  
24 90 kHz. As with the previous example, the two FSK  
25 frequencies  $F_1$ ,  $F_2$  are preferably not multiples of one  
26 another to minimise the occurrence of false  
27 detections. The two frequencies  $F_1$ ,  $F_2$  are typically  
28 also at least a factor of two different. Although  
29 this increases the amount of bandwidth required on  
30 the isolated pipeline 100, the system allows for the  
31 recovery of highly attenuated signals. Where there

1 is significant inductance on the isolated pipeline  
2 100, much lower frequencies may be used. This  
3 reduces the speed of the system, but does not affect  
4 the ability of the system to transmit and receive  
5 data. Low carrier frequencies may be used (in the  
6 order of a few hertz) with very high frequency data  
7 carriers to increase data recovery in noisy  
8 environments, such as those downhole. Where low  
9 frequencies are required, the system may also be used  
10 with fractions of a hertz for the carrier, and a  
11 logic zero frequency of 100 Hz and a logic one  
12 frequency of 350 Hz, for example.

13

14 The frequency used to transmit data to and from the  
15 slave unit 50 is typically several hundred kilohertz  
16 (kHz). For example, the transmit frequencies  $F_1$ ,  $F_2$   
17 from the slave unit 50 to the master 10 may be 200  
18 kHz for a one and 90 kHz for a zero. Thus, if a  
19 logic one is to be transmitted, then the higher of  
20 the two FSK frequencies  $F_1$  (i.e. 200 kHz) will be  
21 transmitted for the duration of the high cycle of the  
22 power waveform, and if a logic zero is to be  
23 transmitted, the lower of the two FSK frequencies  $F_2$   
24 (i.e. 90 kHz) is transmitted for the duration of the  
25 high cycle of the power waveform.

26

27 However, where the isolated pipeline 100 is  
28 particularly noisy, for example where the  
29 transmission system 12 is also used to drive a  
30 downhole motor, it may not be possible to determine  
31 whether a logic one or zero was sent from the basic

1 counter discrimination technique. A further  
2 technique is used to aid in discriminating between a  
3 logic one and zero that sub-divides each of the data  
4 windows in the data transmission waveform into a  
5 series of sub-windows. An example of a sub-window is  
6 shown in Fig. 8d, which is an enlarged view of one of  
7 the data windows from the waveform in Fig. 8c. The  
8 data window is sub-divided into a number of sub-  
9 windows, such as ten shown in Fig. 8d. Each of the  
10 ten sub-windows is then studied and measurements  
11 taken to determine which of the two FSK frequencies  
12 (i.e.  $F_1$  or  $F_2$ ) is present within that sub-window.

13  
14 Every high period (the receive window) of the slave  
15 unit power waveform (Fig. 8c) is segmented in the  
16 processor code into smaller time slots (typically ten  
17 per receive window). When the system is first  
18 initiated, or on command from the master unit 10, the  
19 slave unit 50 transmits a specified pattern of ones  
20 and zeros to calibrate the transmission data windows.  
21 The master unit 10 receives and processes this  
22 pattern and determines from the pattern received the  
23 reliability of the recovered data. The reliability  
24 of the recovered data indicates which of the sub-  
25 windows in the received window has reliably  
26 transmitted a one or a zero. The sub-windows in  
27 which a one or a zero cannot be reliably recovered  
28 are mapped as being "not usable" in the memory of the  
29 processor 20 and are thus not used for data recovery.  
30 In this way, the reliability of the system is  
31 increased, as the test transmission allows the system

1 to assess which sub-windows are being affected by  
2 noise and other interference, these sub-windows then  
3 being ignored for future transmissions. This  
4 technique allows for enhanced reliability and also  
5 the ability to allow the system to be calibrated to  
6 particular environments.

7  
8 Thus, this technique provides a method of data  
9 transmission and recovery that uses sub-divided and  
10 synchronised data recovery windows to enhance the  
11 noise immunity of the system, and also the use of a  
12 calibrating pattern to allow the master unit 10 to  
13 determine the reliable portions of the recovered data  
14 transmitted by the slave unit 10.

15  
16 Referring to Fig. 4, isolating collar 200 is used to  
17 provide electrical isolation whilst maintaining  
18 pressure sealing in the pipeline 100. Isolating  
19 collar 200 is described in US Patent Nos 4,861,074  
20 and 4,716,960 assigned to Production Technologies  
21 Inc, the entire disclosure of these patents being  
22 incorporated herein by reference thereto. The  
23 function of isolating collar 200 is conventionally to  
24 electrically isolate at least a portion of the  
25 pipeline, wherein electrical power is applied to the  
26 pipeline or tubing string to facilitate heating of  
27 the pipeline or tubing string. Heating of the  
28 pipeline or tubing string is to prevent the formation  
29 of solids, particularly for use with pipelines or  
30 tubing strings containing paraffin.

31

1 Isolating collar 200 is provided with threads 204 at  
2 an upper end of an inner connector 202. Threads 204  
3 facilitate connection of the isolating collar 200 to  
4 a tubing string or the like thereabove. Inner  
5 connector 202 is substantially tubular and is  
6 typically of a steel construction with material to  
7 suit the pipeline or tubing string to which it is  
8 attached.

9  
10 Inner connector 202 is provided with a continuous  
11 screw thread 206 on an exterior surface for  
12 engagement with an inner insulating seal sleeve 208.  
13 Inner sleeve 208 is provided with a thread 210 that  
14 allows it to be threadedly coupled to the thread 206  
15 of the inner connector 202, and a thread 212 provided  
16 on the interior of an outer connector 214. Inner  
17 connector 202 is typically provided with sealing  
18 means, such as O-rings 218, at a lower end thereof to  
19 seal against sleeve 208.

20  
21 Outer connector 214 is typically formed of  
22 electrically conducting material such as steel, and  
23 is concentrically attached to the inner connector 202  
24 to be supported thereby. Outer connector 214 is  
25 provided with an internal thread 216 at a distal end  
26 thereof to facilitate connection of the isolating  
27 collar 200 into a pipeline or tubing string attached  
28 therebelow. The distal end of outer connector 214 is  
29 also provided with sealing means, for example O-rings  
30 220, on the inner bore thereof for sealing with the  
31 sleeve 208.

1  
2 An insulating material 222 is typically injected into  
3 an annulus between the inner and outer connectors  
4 202, 214 via a port 226. The insulating material 222  
5 provides for electrical insulation between the inner  
6 and outer connectors 202, 214, and can additionally  
7 provide mechanical strength to support the weight of  
8 the string below the collar 200. The insulating  
9 material may be, for example, an epoxy such as  
10 aromatic amine.

11  
12 The insulating material 222 typically includes sleeve  
13 208 that is typically formed of a plastic material.  
14 Sleeve 208 bridges the space between the lower end of  
15 the inner connector 202 and the seal means 220 and  
16 prevents electrical contact between the inner and  
17 outer connectors 202, 214 through water being  
18 contained within the fluids flowing through the  
19 collar 200.

20  
21 Sleeve 208 and the first and second seals 218, 220  
22 insulate between the inner and outer connectors 202,  
23 214 and additionally prevent fluids from reaching the  
24 insulating material 222 from the interior of the  
25 isolating collar 200. The insulating material 222 is  
26 preferably protected from contact with well fluids  
27 that may cause a short circuit within the isolating  
28 collar 200.

29  
30 In certain embodiments of the isolating collar 200, a  
31 nonsolid, noncompressible material is injected into

1 cavities in the lower end of the isolating collar  
2 200. This material is confined under pressure so  
3 that sleeve 208 is supported against internal  
4 pressure. Thus, as pressure within the bore of the  
5 isolating collar 200 increases, the pressure on the  
6 nonsolid material increases and no substantial  
7 pressure differential is created. The material is  
8 preferably silicone. Before the nonsolid material is  
9 injected, the area that it fills is typically  
10 evacuated.

11  
12 Isolating collar 200 is based on an oilfield thread  
13 for coupling but can be adapted to other pipe  
14 coupling threads and indeed flange couplings without  
15 compromising or altering the core design of the  
16 collar. Thus, those skilled in the art will  
17 appreciate that isolating collar 200 can be coupled  
18 to the pipeline or tubing string in any conventional  
19 manner, depending upon the particular application  
20 and/or the structure of the pipeline or tubing  
21 string.

22  
23 Isolating collar 200 includes a ring 228 that allows  
24 external electrical power and transmissions to be  
25 coupled to the outer connector 214. Ring 228 is  
26 provided with internal threads 230 that engage  
27 external threads 232 on an upper end of the outer  
28 connector 214. A blind conduit 234 is provided on  
29 the ring 228 to allow for connection of electrical  
30 signals using any conventional means. Thus,  
31 electrical signals, such as power and/or

1 communications, may be transmitted via the outer  
2 connector 214 to any receiver that is electrically  
3 coupled to the pipeline or tubing string suspended  
4 below the isolating collar 200.

5  
6 Fig. 5 shows an alternative embodiment of an  
7 isolating collar 300. Collar 300 is substantially  
8 the same as collar 200. Isolating collar 300 is  
9 described in US Patent Nos 4,861,074 and 4,716,960  
10 assigned to Production Technologies Inc, the entire  
11 disclosure of these patents being incorporated herein  
12 by reference thereto.

13  
14 Isolating collar 300 includes an upper connector 302  
15 and a lower connector 304. The upper and lower  
16 connectors 302, 304 are threadedly coupled using  
17 threads 306 on the upper connector 302 and threads  
18 308 on the lower connector 304. It should be noted  
19 that the upper and lower connectors 302, 304 may be  
20 coupled in any conventional manner.

21  
22 The cavity between the threads 306, 308 is preferably  
23 filled with an insulating material 310 as in the  
24 previous embodiment, the material 310 typically being  
25 epoxy. The insulating material 310 typically  
26 provides for electrical insulation between the two  
27 connectors 302, 304, and the interlocking threads  
28 306, 308 give mechanical support to allow a tubing  
29 string to be suspended from the lower connector 304.

30

1 The lower connector 304 is provided with a threaded  
2 bore 312 for receiving an electrical conduit 314.

3

4 The upper and lower connectors 302, 304 are provided  
5 with a central bore 302b, 304b respectively, to allow  
6 the passage of fluids through the collar 300, and  
7 also threads 302t, 304t respectively, to allow the  
8 collar 300 to be coupled into a tubing string or  
9 pipeline.

10

11 The upper connector 302 is provided with a  
12 counterbore 316 that receives the electrical conduit  
13 314. The counterbore 316 is typically filled with  
14 epoxy insulating material when the electrical conduit  
15 314 is in place.

16

17 Electrical conduit 314 typically comprises a metal  
18 rod having a lower threaded end 314l for threadedly  
19 engaging threaded bore 312 in the lower connector 304  
20 to facilitate electrical connection. The conduit 314  
21 has an enlarged diameter portion 314e to reduce the  
22 electrical resistance of the conduit 314 in the area  
23 of the enlarged portion 314e, so that the insulating  
24 material in this area is not overheated when high  
25 power signals are transmitted.

26

27 The electrical conduit 314 is provided with an  
28 electrical connector 318 at its upper end, the  
29 connector 318 being attached by any suitable means,  
30 such as a screw thread. The connector 318 is  
31 provided with a blind internal bore 320 to which

1 electrical connection may be made, for example by  
2 soldering. The connector 318 is typically  
3 electrically insulated by using a rubber boot, for  
4 example, positioned over the connector 318.

5  
6 Thus, both isolating collars 200, 300 facilitate  
7 electrical isolation of the pipeline above the  
8 collars 200, 300 but allow transmission of electrical  
9 signals on the pipeline suspended below the collars  
10 200, 300.

11  
12 In addition to the use of the isolating collar 200,  
13 300 the pipeline system 100 (Fig. 1) is preferably  
14 isolated from electrical ground between the collars  
15 200a, 200b to maintain the isolation. This requires  
16 the pipeline to have a degree of insulation or be  
17 spaced off any grounded objects, by insulating mounts  
18 or protectors, as will be described hereinafter.

19  
20 It will be appreciated that the pipeline 100 is  
21 required to be isolated to some extent from ground.

22  
23 Referring now to Fig. 9, there is shown an oilwell,  
24 generally designated 400, with tubular casing 412 and  
25 a pipe based production tubing. The oilwell  
26 generally includes a well head 402 that may be of any  
27 conventional type, that has a tubing string suspended  
28 therebelow. The tubing string typically comprises a  
29 plurality of tubulars 404 that are coupled together  
30 in a known manner (such as by threaded couplings). A  
31 number of isolating collars 200a, 200b, 200c are

1 coupled into the tubular string at specified  
2 locations, to electrically isolate the tubular  
3 string. The isolating collars 200 may comprise the  
4 isolating collars 300.

5  
6 The master unit 10 can be either directly or  
7 capacitively coupled to the single wire connection to  
8 the downhole system, via the isolating collar 200a.  
9 Power and data transmissions to and from the master  
10 unit 10 are driven between the single live contact  
11 through a wellhead penetrator 406 provided in the  
12 wellhead 402. The wellhead penetrator 406 would be  
13 the type of penetrator used for electrical  
14 submersible pump (ESP) installations or permanent  
15 gauge installations. Fig. 10 shows a typical  
16 penetrator 406, although any proprietary well head  
17 penetration device with suitable pressure and  
18 electrical rating may be used.

19  
20 Referring now to Figs 10a and 10b, the function of a  
21 wellhead penetrator 406 is to allow electrical cables  
22 to be fed through an oil field wellhead 402. The  
23 wellhead 402 forms a pressure cap on the well and so  
24 any electrical penetration has to maintain the  
25 pressure seal of the wellhead 402.

26  
27 Fig 10a illustrates an API flange unit, and Fig. 10b  
28 illustrates an NPT mounted unit, but both units  
29 perform the same function and are substantially the  
30 same. The penetrators 406 include a primary pressure  
31 seal 450 that typically comprises a metal-to-metal

1 seal. Seal 450 couples the body of the penetrator  
2 406 to the wellhead (schematically shown in Figs 10a  
3 and 10b as 452) itself. A seal 454 seals against a  
4 cable running through the wellhead 452 itself, seal  
5 454 typically being a metal-to-metal seal.

6

7 A glass-to-metal electrical penetrator allows  
8 electrical inner conductors to pass through a  
9 pressure-tight barrier 456.

10

11 The penetrator 406 includes a connector 458 to  
12 facilitate coupling of an external cable onto the  
13 wellhead penetrator 406. Connector 458 may comprise  
14 a gland or any other type of cable exit.

15

16 The penetrator 406 may be mounted to the wellhead 452  
17 using any conventional means, such as bolts 460 (Fig.  
18 10a) or a screw thread 462 (Fig. 10b). The wellhead  
19 protector 406 typically includes a pressure-tight  
20 steel body 464 that houses and generally mounts the  
21 major components of the penetrator 406.

22

23 The single wire from the base of the penetrator 406  
24 is fed on to the isolating tubing collar 200a mounted  
25 below the wellhead 402 and a tubing hanger 408 (Fig.  
26 9). Electrical contact between the single wire of  
27 the wellhead penetrator 406 and the isolated portion  
28 of the tubing below the isolating collar 200a can be  
29 achieved by using either of the isolated collars 200,  
30 300 described herein, or otherwise.

31

1     Alternatively, the single wire of the wellhead  
2     penetrator 406 can be coupled directly to any part of  
3     the isolated tubing string using a simple tubing  
4     based connection as shown in Fig. 11. Fig. 11  
5     schematically illustrates the wellhead penetrator 406  
6     and two methods of coupling the wire from the  
7     penetrator 406 to the isolated portion of tubing.  
8     The first method is described above, wherein the  
9     isolating collar 200a is used to transmit electrical  
10    signals from the wellhead penetrator 406 to the  
11    isolated portion of the tubing string.

12  
13    Alternatively, the wire from the wellhead penetrator  
14    406 may be coupled to the isolated pipeline using a  
15    cable coupling (not shown) that is coupled to a  
16    tubing clamp 410.

17  
18    Referring again to Fig. 9, the tubing string is  
19    prevented from touching casing 412 of the oilwell 400  
20    by insulated protectors 414. The insulated  
21    protectors 414 can be mounted at either couplings 416  
22    between successive tubulars 404 or at a mid point 418  
23    in the length of a tubular 404. The insulated  
24    protectors 414 are typically of a rubber or plastic  
25    construction and are commonly used in the oil and gas  
26    industry. They are generally two types of protectors  
27    414, either protecting across the tubing joint (cross  
28    coupling protectors) such as at coupling 416 or  
29    clamping at any point in the pipe (mid joint  
30    protectors) such as at mid point 418.

31

1 The slave units 50 are typically mounted to the  
2 production tubing 404. In this example, two slave  
3 units 50a, 50b are shown. Fig. 9a shows an enlarged  
4 view of a section of the tubing of Fig. 9  
5 illustrating how the slave units 50a, 50b are coupled  
6 to the tubing string. Slave units 50a have a carrier  
7 or mandrel 420 that attaches the slave unit 50a to  
8 the tubing 404, a slave module 422 that contains the  
9 electronic circuitry described above, and an  
10 electrical return path that typically comprises the  
11 casing 424 of the slave unit 50a. Casing 424  
12 typically comprises a spring contact.

13  
14 The slave unit 50a is further illustrated in Fig. 12.  
15 The slave unit 50a is electrically connected to the  
16 tubing 404 by clamping the electronic module 422  
17 containing the circuitry onto the tubing based  
18 mandrel 420. Mandrel 420 may be machined from solid  
19 steel, fabricated or a combination of solid machining  
20 and bolted clamps. The general structure of the  
21 mandrel 420 is of steel to suit the rest of the  
22 tubing string. The electronics of the slave unit 50a  
23 are isolated from a protective pressure housing 426,  
24 housing 426 being conventionally grounded, but being  
25 live in this particular embodiment. The electronic  
26 module 422 mounted to the mandrel 420 has insulated  
27 end pieces 428 that the spring contact 424 is mounted  
28 to. This electrically isolates the spring loaded  
29 contacts 424 from both the mandrel 420 and the body  
30 of the electronic module 422. The slave unit  
31 pressure housing 426 typically supports the spring

1 contact 424 and also maintains pressure integrity  
2 during wiping action of the spring contact 424.

3  
4 Thus, the electronics in the electronics module 422  
5 is coupled between the live pipe or tubing 404 and  
6 the ground potential casing 412 (not shown in Fig.  
7 12), thus drawing power from the live tubing 404.

8  
9 The simplest return path connection is a  
10 spring-loaded wiper arm 424 (Fig. 12), that pushes  
11 against the casing 412 of the well 400. The  
12 electrical return contact can be a hydraulically  
13 operated latching arm (not shown) or alternatively,  
14 may comprise the grips of a hydraulically set packer  
15 (not shown).

16  
17 Thus, the slave units 50 are electrically coupled to  
18 the master unit 10 using only the production tubing  
19 404 and can monitor sensors and control actuators  
20 (not shown) as described above.

21  
22 Furthermore, the telemetry system can be used in a  
23 multi-lateral well (several branches downhole from a  
24 single borehole) and slave units 50 can be installed  
25 in each of the multiple branches (not shown). Thus,  
26 the system may operate with multiple slave units 50  
27 in various branches of the well, with all of the  
28 slave units 50 acting in parallel on the same system,  
29 and with no requirement for any splicing or joint in  
30 the system other than a union on the tubing system  
31 404 that is inherent for the well to function.

1

2 Referring again to Fig. 9, the system is shown as  
3 having multiple slaves 50a, 50b, 50c coupled to the  
4 production tubing 404 at any convenient locations.  
5 The slave units 50a, 50b, 50c may be positioned to  
6 allow for the control, operation and interrogation of  
7 a plurality of different instruments, sensors or load  
8 actuators as required.

9

10 Where a slave unit 50 requires to be mounted below a  
11 packer or valve 430 (which cannot be isolated  
12 electrically from the casing 404) an isolating tubing  
13 collar 200b will be mounted above the packer or valve  
14 430, and a further isolating collar 200c mounted  
15 below the packer or valve 430. A cable 432 is used  
16 to circumvent the packer or valve 430 (or any other  
17 obstructing object) using a standard isolated packer  
18 penetrator 434.

19

20 The slave units 50a, 50b, 50c in this embodiment may  
21 be used for reservoir monitoring using pressure  
22 and/or temperature sensors, flow meters, and fluid  
23 temperature probes. These slave units 50a, 50b, 50c  
24 may also be used to operate and control gas lift  
25 valves, fluid production intake valves and fluid  
26 circulating valves. The slave units 50a, 50b, 50c  
27 may also be used to control a packer with a flow  
28 through valve controlled from the master unit 10.  
29 The telemetry system has the capability to apply  
30 substantial electrical power to downhole actuators  
31 (not shown) due to the low resistance of the pipe 404

1 in the tubing string. Thus, the telemetry system can  
2 be implemented to drive and control large motors,  
3 actuators and the like.

4  
5 In some downhole applications, fluid in the space  
6 between the casing 412 and the outside surface of the  
7 production tubing 404 is conductive. In this case,  
8 the tubing 404 in addition to being spaced from the  
9 casing 412 by the insulating protectors 424, would  
10 also be coated with an insulating paint or the like  
11 to increase the amount of electrical isolation  
12 between the tubing 404 and casing 412.

13  
14 The telemetry system can tolerate a certain degree of  
15 leakage current from the tubing 404 to the casing 412  
16 so that complete coating and full isolation is not a  
17 primary requirement. The leakage tolerance is  
18 achieved by using telemetry signal levels that have  
19 sufficient margin to tolerate this leakage current.

20  
21 Referring now to Figs 13a and 13b, Fig. 13a shows a  
22 subsea pipeline system 500, that includes a dual  
23 pipeline 502, 504, and Fig. 13b illustrates a subsea  
24 pipeline system 550 that includes a single pipeline  
25 552. In Figs 13a and 13b, the pipelines 502, 504,  
26 552 are typically under water (either fresh or sea  
27 water) and the pipelines 502, 504, 552 are used as  
28 the power and communications transmission medium for  
29 the telemetry system.

30

1 The master unit 10 of the telemetry system includes a  
2 power supply and master control unit, and is  
3 typically located above the water level and before  
4 the point where the pipeline 502, 504, 552 enters the  
5 water. The pipelines 502, 504, 552 generally do not  
6 have any other power source present on the pipelines  
7 502, 504, 552 in such applications, and thus it is  
8 not necessary to capacitively couple the master unit  
9 10 to the pipeline 502, 504, 552. Thus, direct  
10 coupling of the ac power from the master unit 10 to  
11 the pipelines 502, 504, 552 may be used. However, it  
12 will be appreciated that capacitive coupling will be  
13 required where the pipelines 502, 504, 552 are used  
14 to carry any other power source.

15  
16 A single or two wire connection is made from the  
17 master unit 10 to a connection point 504 at or near  
18 the isolating collar 200a. At the connection point  
19 504, the live power wire from the master unit 10 is  
20 coupled to an isolated portion 502i of the pipeline  
21 502, by making connection to the metallic body of the  
22 isolated portion 502i of the pipeline 502. The  
23 electrical contact can be made by clamping to the  
24 pipeline 502, or using a modified portion of pipe  
25 with an electrical connector or coupling fitted  
26 thereto, or in any other suitable manner. An  
27 isolating tubing collar 200a in the pipeline 502  
28 electrically isolates the pipeline 502 from a source  
29 506 of the transported fluid, and supports the weight  
30 or tension in the pipeline 502. A second isolating  
31 collar 200b is positioned at or near a delivery end

1 502d of the pipeline 502. The isolating collars  
2 200a, 200b can be either of an oil field thread type,  
3 or may be coupled to the pipeline 502 at the  
4 termination of the dual pipe couplings, where the  
5 couplings may be modified to suit the pipeline  
6 material and coupling method, but the internal  
7 structure of the collars 200a, 200b is as described  
8 above. It should be noted that either of the  
9 isolating collars 200, 300 may be used.

10

11 In this way, a transmission zone 502z is defined  
12 between the isolating collars 200a, 200b. The master  
13 unit 10 is electrically coupled to the transmission  
14 zone 502z using the isolating collar 200a, for  
15 example, as described above. Slave units 50a, 50b  
16 can then be electrically coupled at any point within  
17 the transmission zone 502z so that any power and/or  
18 data transmissions from the master unit 10 (or data  
19 transmissions from the slave units 50a, 50b to the  
20 master unit 10) can be retrieved.

21

22 The isolated portion 502i of the pipeline 502 is  
23 insulated partially from the water by both coating of  
24 the pipeline 502 and insulating protectors 510. The  
25 coating can be selected from any of a number of  
26 available techniques. The insulating coatings  
27 typically provide a substantial fluid resistance, and  
28 complete water sealing is preferable but not  
29 essential. Similarly, at pipe joints under water in  
30 the pipeline 502, the joints should be covered with  
31 plastic or rubber insulating covers to provide

1 protection against physical damage, any electrical  
2 shorting and also water ingress into the joints.  
3 Injection of insulating grease or sealant into the  
4 joint covers is again preferable but not necessary.

5  
6 At any point in the transmission zone 502z, slave  
7 units 50a, 50b can be attached to provide monitoring  
8 of sensors or control of actuators as described  
9 above. Any number of slave units 50 may be coupled  
10 into the system as required.

11  
12 Referring to Fig. 14, the slave units 50a, 50b are  
13 typically mounted so that the units 50a, 50b make  
14 electrical contact with the live metal of the  
15 transmission zone 502z. If the body of the  
16 protective pressure housing 426 (Fig. 14) is attached  
17 to the metal of the pipe 502, 504, 552 then it will  
18 be live and will require an isolated ground contact  
19 that is connected to the local ground 554 (Fig. 13b)  
20 or second pipeline 504 (Fig. 13a) that are used as  
21 ground returns. The ground contact is typically made  
22 by attaching a fly lead 436 to one of the insulated  
23 end pieces 428, and thus end pieces 428 are typically  
24 grounded. The protective pressure housing 426  
25 typically protects the electronics from the water  
26 pressure, and additionally isolates the ground  
27 contact from the live pipe 502, 504, 552.

28  
29 The slave units 50 require a ground or earth to  
30 complete the electrical circuit. This can be  
31 achieved using local grounding 554 such as the

1 seabed, a lake bed or the like, schematically  
2 illustrated in Fig. 13b. Alternatively, this may  
3 also be achieved by using another pipeline 504  
4 running next to the "live" one as the ground return,  
5 schematically illustrated in Fig. 13a.

6  
7 The slave unit 50 located underwater can have several  
8 functions including strain gauge measurement on  
9 pipeline stress, lifting forces from riser buoyancy  
10 elements, fluid temperature measurement, flow rate  
11 measurement in co-mingled lines, or the like.  
12 Further uses could be to provide control of a subsea  
13 installed wellheads using the underwater pipeline as  
14 the only power and communications medium. The  
15 functionality of the slave unit 50 could include the  
16 control of wellhead actuators, measurement of choke  
17 positions and measurement of local pressure and  
18 temperatures.

19  
20 A further use of this system would include coupling  
21 an underwater acoustic modem to the slave unit 50 to  
22 allow interrogation of long pipeline sensor systems  
23 from floating rigs, FPSO and ships while working on  
24 the pipe line 502, 504, 552 or associated systems.

25  
26 Referring now to Figs 15a and 15b, there is shown a  
27 dual and single pipeline system 600, 650  
28 respectively, that are typically located on the  
29 surface. The master unit 10 includes a power supply  
30 and master control unit and is typically located near  
31 the source 610 of the pipeline 602, 604, 650, or

1 coupled to the pipeline 602, 604, 652 using a  
2 suitable cable. An isolating tubing collar 200a is  
3 coupled into the pipeline 602, 652 to isolate the  
4 pipe 602, 652 from the source 606 of the transported  
5 fluid, and support the pipeline 602, 652. In  
6 addition, there is a second isolating collar 200b  
7 positioned at the delivery end 602d, 652d of the  
8 pipeline 602, 652. Either isolating collar 200 or  
9 collar 300 may be used.

10

11 The live or power line from the master unit 10 is  
12 coupled to an isolated section 602i, 652i of the  
13 pipeline 602, 652 using a clamp or connector to  
14 attach to the steel of the pipeline 602, 652, similar  
15 to the embodiments shown in Figs 13a and 13b. The  
16 isolated section 602i, 652i of the pipeline 602, 652  
17 is insulated partially from the weather and/or the  
18 surrounding surface by both coating of the pipeline  
19 602, 652 and insulating protectors 610. The coating  
20 and insulating joint protectors 610 typically provide  
21 a substantially water-tight cover. It is not a  
22 requirement that the coating and protectors 610 are  
23 completely water-tight.

24

25 In this way, a transmission zone 602z is defined  
26 between the isolating collars 200a, 200b. The master  
27 unit 10 is electrically coupled to the transmission  
28 zone 602z using the isolating collar 200a, for  
29 example, as described above. Slave units 50a, 50b  
30 can then be electrically coupled at any point within  
31 the transmission zone 602z so that any power and/or

1 data transmissions from the master unit 10 (or data  
2 transmissions from the slave units 50a, 50b to the  
3 master unit 10) can be retrieved  
4

5 Where the pipeline 602, 652 is on the surface, the  
6 pipeline 602, 652 is supported along its length by  
7 insulating supports (not shown) to prevent it from  
8 grounding to earth. These supports are typically  
9 fabricated from standard supports with isolating  
10 rings to space the mounting from the pipeline 602,  
11 652.  
12

13 As before, a slave unit 50 can be coupled to the  
14 transmission zone 602z, 652z at any point along its  
15 length, and multiple slave units 50 may be used.

16 Slave units 50a, 50b can be coupled to the  
17 transmission zone 602z, 652z to provide monitoring of  
18 sensors or control of actuators, as described above.  
19

20 Referring now to Fig. 16, the slave units 50a, 50b  
21 would typically be mounted on a grounded structure  
22 (not shown) around the pipeline 602, 652 and a single  
23 wire 620 run to a clamp 622 or connector connecting  
24 the slave unit 50a, 50b live connect to the metal of  
25 the pipeline 602, 652.  
26

27 The slave units 50 require a ground or earth to  
28 complete the electrical circuit. This can be  
29 achieved by either using local grounding 624 like the  
30 earth (schematically illustrated in Figs 15b and 16),  
31 or may also be achieved by using another pipeline 604

1 running next to the "live" one as the ground return  
2 (as illustrated in Figs 15a and 16).  
3

4 The slave unit 50 can perform a plurality of  
5 functions in relation to a surface pipeline 602, 652,  
6 such as fluid flow measurement, valve control, pipe  
7 corrosion or strain measurement, fluid composition  
8 measurement, pressure, temperature, vibration and  
9 also pipe inclination for subsidence monitoring.  
10 Shut down valves could also be driven from a slave  
11 unit 50 as well as control of pumps and drain or  
12 bleed valves to control fluid pumping or control  
13 equipment remotely using the pipeline 602, 652 as the  
14 control link.  
15

16 This particular embodiment is useful for controlling  
17 remote pumping stations where the station is far  
18 removed from electrical power and/or telephone lines.  
19 The telemetry system can provide both power to the  
20 pumps, and also the ability to measure and control  
21 the pumping operation.  
22

23 Fig. 17 illustrates a surface pipeline comprising  
24 first and second isolated pipelines 702, 704 (similar  
25 to the system shown in Figs 13a, 13b), and an  
26 isolated subsea or downhole tubing 706 (similar to  
27 the system shown in Fig. 9). An oilwell 708 which  
28 has a wellhead 712 on the surface has the isolated  
29 pipelines 702, 704 coupled thereto from the surface,  
30 and on the same system has the isolated downhole  
31 production tubing 706 suspended therebelow.

1  
2 The pipeline 702 from the surface is isolated with an  
3 isolating tubing collar 200a at the surface, and a  
4 second isolating collar 200b is provided at or near  
5 the wellhead 712, creating a transmission zone  
6 therebetween. An electrical link 714 couples the  
7 power and data transmissions from the isolated supply  
8 from the surface pipeline 702 to a wellhead  
9 penetrator 716 and this in turn couples the power and  
10 data transmissions to the isolated downhole tubing  
11 706. The downhole tubing 706 typically has at least  
12 one slave unit 50 coupled thereto (Fig. 17 shows two  
13 slave units 50a, 50b) that are connected back to  
14 electrical ground through the downhole casing 718.  
15 As before, slave units 50c and 50d can be coupled  
16 anywhere in the isolated transmission zone of the  
17 surface pipeline 702, or the downhole tubing 706.  
18 The slave units 50c, 50d may use the second pipeline  
19 704 as a ground return, or may be grounded locally,  
20 depending upon the application and/or the location of  
21 the slave units 50c, 50d.

22  
23 A further extension of this system would be to use a  
24 single subsea pipeline (not shown) to couple several  
25 downhole wells together on the same system. This  
26 would also apply where the oilwell had multi-lateral  
27 bore holes and each arm of the multi-lateral system  
28 was both isolated and connected to the same power  
29 source. The system would have the ability to supply  
30 substantial levels of power to drive the electronics

1 and controls at each of the wells that are coupled to  
2 the slave units 50.

3

4 Thus, there is provided a telemetry system that in  
5 certain embodiments allows for both power and data  
6 transmissions across an isolated tubing string or  
7 pipeline. The system in certain embodiments uses  
8 frequency-shift keying (FSK) and pulse-width  
9 modulation to allow for the transmission of data  
10 across the pipeline or tubing string.

11

12 The system in certain embodiments is flexible in that  
13 it allows for a number of slave units to be located  
14 remotely from one or more master units, the master  
15 units being used to control the operation of the  
16 slave units. The slave and master units are  
17 typically coupled to a single transmission medium,  
18 such as the isolated pipeline or tubing string. The  
19 system in certain embodiments can also support the  
20 use of more than one master unit to control the slave  
21 units from more than one point within the system.

22

23 There is also provided a method of transmitting  
24 pulse-width modulated power over an isolated pipeline  
25 or tubing string and recovering this as both power  
26 and data. There is also provided a method of  
27 transmitting frequency-shifted data that is  
28 synchronised to a received power waveform.

29

- 1 Modifications and improvements may be made to the
- 2 foregoing, without departing from the scope of the
- 3 present invention.

1     **CLAIMS**

2     1.    A telemetry system comprising a master unit, and  
3     at least one slave unit remote from the master unit,  
4     the master and slave units communicating via a  
5     transmission system, wherein the telemetry system is  
6     capable of transmitting power and data transmissions  
7     between the units, and wherein the transmission  
8     system includes an at least partially isolated tubing  
9     string or pipeline.

10

11    2.    A telemetry system according to claim 1, wherein  
12    the pipeline or tubing string is electrically  
13    isolated using at least one isolating collar.

14

15    3.    A telemetry system according to claim 2, wherein  
16    the isolating collar comprises first and second  
17    connectors, the first and second connectors being  
18    threadedly coupled together.

19

20    4.    A telemetry system according to claim 3, wherein  
21    an electrical isolating material is injected between  
22    the first and second connectors to isolate the  
23    connectors from one another.

24

25    5.    A telemetry system according to claim 3 or claim  
26    4, wherein the isolating collar includes means for  
27    conveying electrical signals from outwith the collar  
28    to the second connector.

29

30    6.    A telemetry system according to any preceding  
31    claim, wherein the pipeline or tubing string is

1 coated with an electrically isolating coating to at  
2 least partially isolate the pipeline or tubing  
3 string.

4  
5 7. A telemetry system according to any preceding  
6 claim, wherein the at least partially isolated  
7 pipeline or tubing string comprises a surface  
8 pipeline or tubing string.

9  
10 8. A telemetry system according to any one of  
11 claims 1 to 7, wherein the at least partially  
12 isolated pipeline or tubing string comprises a subsea  
13 pipeline or tubing string, or a downhole pipeline or  
14 tubing string.

15  
16 9. A telemetry system according to any preceding  
17 claim, wherein the at least partially isolated  
18 pipeline or tubing string comprises any combination  
19 of surface, subsea or downhole pipelines or tubing  
20 strings.

21  
22 10. A telemetry system according to any preceding  
23 claim, wherein the pipeline or tubing string includes  
24 a first isolating collar at or near a source of fluid  
25 flowing within the pipeline or tubing string.

26  
27 11. A telemetry system according to claim 10,  
28 wherein the pipeline or tubing string includes a  
29 second isolating collar at or near a sink for the  
30 fluid in the pipeline or tubing string.

31

1 12. A telemetry system according to claim 10 or  
2 claim 11, wherein the master unit is electrically  
3 coupled to the pipeline or tubing string via the  
4 first isolating collar.

5  
6 13. A telemetry system according to any preceding  
7 claim, wherein at least one slave unit is coupled to  
8 the pipeline or tubing string.

9  
10 14. A telemetry system according to any preceding  
11 claim, wherein the slave unit comprises a mandrel, a  
12 slave module, and an electrical return path.

13  
14 15. A telemetry system according to claim 14,  
15 wherein the mandrel facilitates attachment of the  
16 slave unit to the pipeline or tubing string.

17  
18 16. A telemetry system according to claim 14 or claim  
19 15, wherein the mandrel facilitates transmission of  
20 the electrical power and data transmissions from the  
21 pipeline or tubing string to the electronics of the  
22 slave unit.

23  
24 17. A telemetry system according to any one of  
25 claims 14 to 16, wherein the slave module houses the  
26 electronics of the slave unit.

27  
28 18. A telemetry system according to any one of  
29 claims 14 to 17, wherein the electrical return path  
30 comprises a spring contact for engaging an earth  
31 point.

1

2 19. A telemetry system according to claim 18,  
3 wherein the earth point is a local earth, a further  
4 tubular such as a second pipeline, a subsea or  
5 surface casing, or a casing of a downhole well.

6

7 20. A telemetry system according to any preceding  
8 claim, wherein pulse-width modulation is used to  
9 facilitate data transmission from the master unit to  
10 the slave unit.

11

12 21. A telemetry system according to claim 20,  
13 wherein the power transmission is modulated with the  
14 data transmission using pulse-width modulation.

15

16 22. A telemetry system according to any preceding  
17 claim, wherein frequency-shift keying (FSK) is used  
18 to facilitate data transmission from the slave unit  
19 to the master unit.

20

21 23. A telemetry system according to claim 22,  
22 wherein the FSK frequencies are superimposed on a  
23 carrier frequency.

24

25 24. A telemetry system according to claim 23,  
26 wherein the carrier frequency is the same frequency  
27 as the power transmission frequency.

28

29 25. A telemetry system according to any one of  
30 claims 22 to 24, wherein the data transmission is

1     synchronised to the "high" cycle of the power  
2     transmission.

3

4     26. A telemetry system according to any one of  
5     claims 22 to 25, wherein the data transmission is  
6     synchronised to the "low" cycle of the power  
7     transmission.

8

9     27. A telemetry system according to any one of  
10    claims 22 to 26, wherein the data transmission is  
11    synchronised to both the high and the low cycles of  
12    the power transmission.

13

14    28. A telemetry system according to any preceding  
15    claim, wherein more than one slave unit is used.

16

17    29. A telemetry system according to claim 28,  
18    wherein the data transmission from the master unit to  
19    the slave unit includes an address of the slave unit.

20

21    30. A telemetry system according to claim 29,  
22    wherein the data transmissions include data error  
23    detection and/or correction.

24

25    31. A telemetry system according to claim 30,  
26    wherein the data error detection and/or correction  
27    comprises a Hamming code.

28

29    32. A telemetry system according to any preceding  
30    claim, wherein the master unit comprises a processor  
31    to control the operation of the master unit; a power

1 waveform generator; and signal recovery and  
2 conditioning circuitry.

3

4 33. A telemetry system according to claim 32,  
5 wherein the processor applies pulse-width modulation  
6 to the power transmission when data transmission is  
7 required from the master unit to the slave unit.

8

9 34. A telemetry system according to claim 32 or  
10 claim 33, wherein when not transmitting data, the  
11 processor defaults the power transmission to a 50%  
12 duty cycle.

13

14 35. A telemetry system according to any one of  
15 claims 32 to 34, wherein the signal recovery and  
16 conditioning circuitry allows data transmitted by the  
17 at least one slave unit to be extracted and recovered  
18 from the transmission system.

19

20 36. A telemetry system according to any preceding  
21 claim, wherein the slave unit comprises a processor  
22 to control the operation of the slave unit;  
23 rectifying and regulating circuitry in a first  
24 channel; recovery and conditioning circuitry in a  
25 second channel; and frequency generating and mixing  
26 means.

27

28 37. A telemetry system according to claim 36,  
29 wherein the frequency mixing and generating means  
30 typically comprises a frequency-shift keying (FSK)  
31 generator; an FSK mixer; and a line driver.

1  
2 38. A method of transmitting power and data from a  
3 master unit to at least one slave unit remote from  
4 the master unit, the master and slave units  
5 communicating via a transmission system, the  
6 transmission system including an at least partially  
7 isolated pipeline or tubing string, the method  
8 comprising the steps of  
9       generating a power transmission at the master  
10       unit;  
11       generating a data transmission and synchronising  
12       the data transmission with the power  
13       transmission at the master unit;  
14       transmitting the power and data transmissions  
15       via the transmission system to the slave unit;  
16       and  
17       recovering the power and data transmissions at  
18       the slave unit.

19  
20 39. A method of transmitting data to a master unit  
21 from at least one slave unit remote from the master  
22 unit, the master and slave units communicating via a  
23 transmission system, the transmission system  
24 including an at least partially isolated tubing  
25 string or pipeline, the method comprising the steps  
26 of  
27       generating a power transmission at the master  
28       unit and transmitting the power transmission to  
29       the slave unit;  
30       recovering the power transmission at the slave  
31       unit;

1       generating a data transmission at the slave unit  
2       and synchronising the data transmission with the  
3       power transmission;  
4       transmitting the data transmission via the  
5       transmission system to the master unit; and  
6       recovering the data transmission at the master  
7       unit.

8  
9       40. A method according to either claim 38 or claim  
10      39, wherein the method includes the further steps of  
11       dividing the data transmission into a series of  
12      sub-windows;  
13       transmitting a specified data transmission from  
14      the slave unit to the master unit;  
15       receiving the specified data transmission at the  
16      master unit;  
17       determining which of the sub-windows reliably  
18      transmitted the specified data transmission.

19  
20      41. A method according to claim 40, wherein the sub-  
21      windows that did not reliably transmit data are  
22      filtered out or ignored for subsequent transmissions.

23  
24      42. A method of receiving and converting power and  
25      data transmissions sent from a master unit to at  
26      least one slave unit remote from the master unit, the  
27      master and slave units communicating via a  
28      transmission system, the transmission system  
29      including an at least partially isolated pipeline or  
30      tubing string, the method comprising the steps of

1           receiving a power transmission at the slave  
2 unit;  
3           dividing the power transmission into two  
4 channels;  
5           rectifying and regulating the power transmission  
6 in a first channel; and  
7           recovering the data transmission in a second  
8 channel.

9  
10   43. A method of receiving data transmitted by a  
11 master unit from at least one slave unit remote from  
12 the master unit, the master and slave units  
13 communicating via a transmission system, the  
14 transmission system including an at least partially  
15 isolated pipeline or tubing string, the method  
16 comprising the steps of  
17           receiving the data transmission at the master  
18 unit;  
19           filtering and conditioning the data  
20 transmission; and  
21           regenerating the transmitted data.

22  
23   44. A method according to either claim 42 or claim  
24 43, wherein the method includes the further steps of  
25           dividing the data transmission into a series of  
26 sub-windows;  
27           transmitting a specified data transmission from  
28 the slave unit to the master unit;  
29           receiving the specified data transmission at the  
30 master unit;

1           determining which of the sub-windows reliably  
2           transmitted the specified data transmission.

3

4           45. A method according to claim 44, wherein the sub-  
5           windows that did not reliably transmit data are  
6           ignored or filtered out for subsequent transmissions.

7

8           46. A method according to any one of claims 38 to  
9           45, wherein pulse-width modulation is used to  
10          facilitate data transmission from the master unit to  
11          the slave unit or vice versa.

12

13          47. A method according to claim 46, wherein the  
14          power transmission is modulated with the data  
15          transmission using pulse-width modulation.

16

17          48. A method according to any one of claims 38 to  
18          47, wherein frequency-shift keying (FSK) is used to  
19          facilitate data transmission from the slave unit to  
20          the master unit or vice versa.

21

22          49. A method according to claim 48, wherein the FSK  
23          frequencies are superimposed on a carrier frequency.

24

25          50. A method according to claim 49, wherein the  
26          carrier frequency is the same frequency as the power  
27          transmission frequency.

28

29          51. A method according to any one of claims 38 to  
30          50, wherein the data transmission is synchronised to  
31          the "high" cycle of the power transmission.

1

2 52. A method according to any one of claims 38 to  
3 51, wherein the data transmission is synchronised to  
4 the "low" cycle of the power transmission.

5

6 53. A method according to any one of claims 38 to  
7 52, wherein the data transmission is synchronised to  
8 both the low and high cycles of the power  
9 transmission.

10

11 54. A method according to any one of claims 38 to  
12 53, wherein the data transmissions include data error  
13 detection and/or correction.

14

15 55. A method according to claim 54, wherein the data  
16 error detection and/or correction comprises a Hamming  
17 code, or other suitable technique.
